

Budding

A type of **asexual reproduction** in which a small outgrowth (**bud**) develops on the parent body, grows by **repeated cell division**, and finally detaches to form a **new individual**.

Examples: Hydra & Yeast

Budding in Yeast

Budding in Hydra

Q. Identify the mode of asexual reproduction in the following organism:

- (a) Fragmentation
- (b) Multiple fission
- ☒ (c) Budding
- (d) Binary fission

Check yourself

Q. Assertion (A): Hydra reproduces asexually by budding.

Reason (R): A small outgrowth develops on the parent body due to repeated cell division and later separates as a new individual.

- ☒ (a) Both A and R are true, and R is the correct explanation of A.
- (b) Both A and R are true, but R is not the correct explanation of A.
- (c) A is true, but R is false.
- (d) A is false, but R is true.

Spore Formation

A type of asexual reproduction in which new individuals are formed from tiny spores produced inside special reproductive structures called sporangia.

In Rhizopus (bread mould):

- The thread-like structures on bread are hyphae (non-reproductive).
- The tiny blob-on-a-stick structures are sporangia.
- Sporangia contain spores which can develop into new individuals.
- Spores have thick protective walls that help them survive unfavourable conditions.
- When spores land on a moist surface, they germinate and grow into a new Rhizopus.

Advantages of Spore Formation:

- **Large number of spores** are produced at a time, increasing the chances of survival.
- **Spores have thick protective walls**, which help them survive unfavourable conditions.
- Spores are **light and easily dispersed by air to new places**.
- When they **reach favourable conditions**, they germinate and develop into new individuals.

Check yourself

Ques: How will an organism be benefitted if it reproduces through spores?
[NCERT]

Ans. Spore formation is advantageous because spores have thick protective walls that help them survive unfavourable conditions. They remain dormant and germinate when favourable conditions return, forming new individuals.

Check yourself

Q. Name the reproductive and non-reproductive parts of bread mould (Rhizopus).

Check yourself

Q. Which of the following conditions are responsible for the rapid spread of bread mould?

- ✓ 1. Production of a large number of spores
- ✗ 2. Presence of moisture and nutrients
- 3. Low temperature
- 4. Presence of hyphae

2015, 2016, 2017, 2018, 2020, 2023, 2024

Q.Explain reproduction by spores in Rhizopus with the help of a labelled diagram. Why does Rhizopus not multiply on a dry slice of bread?

Rhizopus (bread mould) reproduces by spore formation.

It has thread-like structures called hyphae, which form a cotton-like mass called mycelium.

At the tip of upright hyphae, sporangia develop that contain numerous spores.

When the sporangium bursts, spores are released into the air.

Under favourable conditions (moisture, warmth, and nutrients), each spore germinates to form a new fungus.

Reason:

Rhizopus does not multiply on dry bread because moisture is essential for spore germination (Dry conditions prevent the spores from growing.)

Q. Select the option having correct matching of the organism given in Column I with the mode of reproduction in Column II:

- (a) P-4, Q-2, R-1, S-3
- (b) P-3, Q-4, R-5, S-2
- (c) P-3, Q-4, R-1, S-2
- (d) P-4, Q-3, R-2, S-1

Column I	Column II
P. Leishmania	1. Regeneration
Q. Spirogyra	2. Multiple Fission
R. Planaria	3. Binary Fission
S. Plasmodium	4. Fragmentation
	5. Budding

Vegetative Propagation

A type of asexual reproduction in which roots, stems, or leaves of a plant develop into a new plant under suitable conditions.

Parts of a Plant

Reproductive part

This part of the plant (flower) which is involved in the process of sexual reproduction.

Vegetative part

These parts of the plant (stem, leaf, root) are not involved in the process of sexual reproduction.

Natural Vegetation

Plants can reproduce naturally without human interference through their roots, stems, or leaves. New plants develop from these parts of the parent plant.

Mode of Vegetative Propagation	Organism / Example
<u>By Underground Stem (Tubers)</u>	Potato
<u>By Roots (Tuberous Roots)</u>	Sweet Potato, <u>Dahlia</u>
<u>By Leaves (Leaf Buds)</u>	<u>Bryophyllum</u> , Kalanchoe

Artificial Vegetative Propagation:

It is the man-made, human-controlled method of reproduction in which new plants are produced from vegetative parts (stem, root, leaf) of the parent plant using special techniques.

Cutting:

- A piece of stem or leaf is cut and planted in soil to grow a new plant. Examples: Rose, Hibiscus, Money plant, Sugarcane.

Grafting:

- In grafting, the stem/branch of one plant called the scion is joined to the rooted plant called the stock. They grow together as a single plant. Examples: Mango, Apple, Rose, Grapes.

P.K → Mango

DSR → Apple

Layering:

- A branch of a plant is bent to the ground and covered with moist soil.
- Roots develop and the buried branch grows into a new plant.
- Example: Jasmine, Rose, Grapes.

Tissue Culture:

- A few cells or tissues are grown in a nutrient medium under laboratory conditions to produce new plants.
- Useful for producing a large number of plants quickly.
- Example: Ornamental plants.

Advantages of Vegetative Propagation

- It is a quick, easy, and cheap method of producing a large number of plants in a short time.
- Genetically identical plants (clones) to the parent can be produced.
- Plants produced by this method have a high survival rate.
- Desired characteristics of plants (such as colour, taste, resistance, fragrance, etc.) can be preserved and passed on.
- It helps in the production of disease-free plants (especially through techniques like micropropagation/tissue culture).
- Some plants that do not produce viable seeds or take a long time to mature can be propagated easily by this method.

Disadvantages of Vegetative Propagation

- No genetic variation in offspring.
- Diseases of parent get transmitted to new plants.
- Not possible in all plants, only certain species.

Check yourself

Ques: Assertion: Vegetative propagation is useful for producing plants that retain the characteristics of the parent.

Reason: Plants produced through this method are genetically similar enough to the parent to retain its characteristics.

A

Check yourself

Q. Why is vegetative propagation practised for growing some types of plants? [NCERT]

Ans. Vegetative propagation is practised because:

- It helps grow plants that do not produce viable seeds.
- New plants are genetically similar to the parent plant, so desirable characteristics are preserved.
- Such plants generally grow, flower and bear fruits earlier than plants grown from seeds.

Check yourself

Q. A gardener plants seeds collected from a healthy mango tree. After a few years, all the new plants resemble the parent tree, but none of them are completely identical. Which statement best explains this observation?

- ☒ (a) The offspring inherit no characteristics from the parent.
- ☒ (b) Reproduction produces offspring that are similar to, but not exact copies of, their parents.
- (c) All plants produced from seeds are genetically identical.
- (d) All similarities between the parent and offspring are due only to environmental effects.

2016, 2017, 2019, 2020, 2023, 2024, 2025

Q. The plants that can be raised by the method of vegetative propagation are:

- (a) Sugarcane, roses, grapes
- (b) Sugarcane, mustard, potato
- (c) Banana, orange, mustard
- (d) Papaya, mustard, potato

Check yourself

- Q. (i) Sugarcane does not produce seeds so name the process through which it will be able to reproduce. ✓
 (ii) List any two advantages of this method. ✓
 (iii) Besides sugarcane, give two more examples of plants that reproduce by this method.

(i) Vegetative propagation.

(ii) Advantages: Plants raised by vegetative propagation can bear flowers and fruits earlier than those produced from seeds. Plants produced by vegetative propagation are genetically similar to the parent plant. Plants that have lost the capacity to produce seed can reproduce by vegetative propagation. (any two)

(iii) Roses, grapes, banana, orange, jasmine etc. (any two examples)

Check yourself

HW

Q. A plant breeder wants to rapidly multiply a plant that has lost its ability to produce seeds. The new plants should retain the characteristics of the parent plant and may produce flowers and fruits earlier than plants grown from seeds.

- (a) Which method of reproduction should the breeder use?
- (b) Name any two vegetative parts of a plant that can be used in this method.
- (c) State one additional advantage of this method.

(a) Vegetative propagation.

(b) Stem and root. (Leaf can also be used.)

(c) It helps produce a large number of genetically similar plants in a short time.

Check yourself

Q. 2015, 2016, 2017, 2019, 2020, 2022, 2024, 2025

Q.(i) What happens when:

(1) Leaves of Bryophyllum fall on the soil?

(2) Planaria is cut into many pieces.

(3) Sporangia of Rhizopus on maturation liberate spores? Mention the modes of reproduction in each of the above three cases.

Case	What Happens	Mode of Reproduction
(1) <i>Leaves of Bryophyllum</i> fall on the soil	Buds present along the leaf margins grow into new plants.	Vegetative Propagation (by leaves)
(2) <i>Planaria</i> is cut into many pieces	Each piece regenerates into a complete organism.	Regeneration
(3) <i>Sporangia of Rhizopus</i> liberate spores	Spores germinate under favourable conditions to form new fungal individual	Spore Formation

Check yourself

Q. (a). Observe the given diagram and answer the questions that follow:[5 Marks]

HW

- (i) Give the name of the structure and type of reproduction shown in the above diagram.
- (ii) State one advantage and one disadvantage of the above mentioned method of reproduction.
- (iii) Give reason: Asexual reproduction lacks genetic variation.
- (iv) Why have higher organisms resorted to sexual reproduction in spite of its complexity?

Mode of Asexual Reproduction	Example(s)	Main Features / Description
Binary Fission	<i>Amoeba, Leishmania</i>	Parent cell divides into two equal halves . In <i>Amoeba</i> division can occur in any plane ; in <i>Leishmania</i> it occurs in a definite orientation along the flagellum.
Multiple Fission	<i>Plasmodium</i>	Parent cell divides into many daughter cells simultaneously, usually inside a cyst during unfavourable conditions.
Fragmentation	<i>Spirogyra</i>	The body breaks into fragments on maturation; each fragment grows into a new individual under favourable conditions.
Regeneration	<i>Hydra, Planaria</i>	Cut or broken body parts can grow into complete organisms using specialised cells that multiply and differentiate.
Budding	<i>Hydra, Yeast</i>	A small bud develops on the parent body, grows, and detaches to form a new individual.
Spore Formation	<i>Rhizopus</i> (bread mould)	Sporangia form spores with thick protective walls ; on release and in moisture, spores germinate into new organisms .
Vegetative Propagation	<i>Potato, Bryophyllum, Sweet Potato</i>	New plants arise from vegetative parts (stem, leaf, root) of the parent plant; helps preserve desirable traits.

Bye Bye!
